VERSION WITH MARKINGS TO SHOW CHANGES MADE

In the Abstract

The Abstract has been amended as follows:

--An electrochemical analyte sensor [formed using] having conductive traces on a substrate [can be] is used [for determining and/or monitoring] to determine a level of analyte in *in vitro* or *in vivo* analyte-containing fluids. [For example, an implantable sensor may be used for the continuous or automatic monitoring of a level of an analyte, such as glucose, lactate, or oxygen, in a patient.] The electrochemical analyte sensor includes a substrate and conductive material disposed on the substrate, the conductive material forming a working electrode. In some sensors, the conductive material is disposed in recessed channels formed in a surface of the sensor. An electron transfer agent and/or catalyst may be provided to facilitate the electrolysis of the analyte or of a second compound whose level depends on the level of the analyte. A potential is formed between the working electrode and a reference electrode or counter/reference electrode and the resulting current is a function of the concentration of the analyte in the [body] fluid.--
